### An Algorithm For Stability Determination

In the mathematical subfield of numerical analysis, numerical stability is a generally desirable property of numerical algorithms. The precise definition of stability depends on the context. One is numerical linear algebra and the other is algorithms for solving ordinary and partial differential equations by discrete approximation. In numerical linear algebra the principal concern is instabilities caused by proximity to singularities of various kinds, such as very small or nearly colliding eigen

Stability, also known as algorithmic stability, is a notion in computational learning theory of how a machine learning algorithm is perturbed by small changes to its inputs. A stable learning algorithm is one for which the prediction does not change much when the training data is modified slightly. For instance, consider a machine learning algorithm that is being trained to recognize handwritten letters of the alphabet, using 1000 examples of handwritten letters and their labels ("A" to "Z" ...

In this paper, a constructive algorithm for a rigorous stability analysis of the equilibrium point of the above-mentioned system is presented. This algorithm has been developed on the basis of a method proposed in [1]. The main idea of this method is to construct and normalize a symplectic map generated by the phase flow of a Hamiltonian system.

This paper conducts the stability analysis of the SSTT system using two recently developed model-based integration algorithms with controllable numerical energy dissipation, i.e., the KR- $\alpha$  and the MKR- $\alpha$  algorithms. The formulation of the SSTT system using the two families of algorithms are derived.

To reflect this continuity, an algorithm should ensure that small changes in the input data should lead to small changes in the output. We say that algorithms which have this property are stable, and the stability of an algorithm can act as a measure for how well an algorithm can preserve the continuous changes in the data.
